Job insecurity

ABSTRACT

The article illuminates one of the central concerns in organizational study; the extent to which job insecurity (JI) affects employees' subjective well-being (SWB) and consequently their job performance (JP) in hospitality industry. Building on the transactional theory stress and coping, the study analyses the buffering role of psychological capital (PsyCap) as a strategy by which employees overcome the negative impact of JI on SWB and JP. Respondents include 250 four and five star hotel employees in Tehran, Iran. The results highlighted the mediating role of SWB, affirming that JI negatively impacts employees' JP via decreasing their SWB. Furthermore, the results show that employees with high level of PsyCap are able to cope with JI. Hotel management teams should make appropriate decisions to minimize or eliminate stressful stimuli, particularly JI in the workplace, which has been found to have severe mental, emotional and behavioural consequences.

1. Introduction

Despite the rising rate of employment in the tourism industry in many countries (Crotti and Misrahi, 2017), job insecurity (JI) still remains a major problem, which has resulted in a performance management dilemma among employees. The results of a study on hotel salespeople in Iran have demonstrated that 53.2% of employees experienced job insecurity (Bouzari and Karatepe, 2018). Similarly, 80% of hotel front-line employees in Northern Cyprus (Darvishmotevali et al., 2017), 41.8% of hotel customer-contact employees in Turkey (Etehad and Karatepe, 2018), 42% of employees in hotels, restaurants and tourist agencies in Serbia, and 56.8% of Korean service employees (Shin and Hur, 2019) suffer from JI. Due to its importance, JI has been one of the most widely researched subjects in the work-related stress field in the hospitality context (Bouzari and Karatepe, 2018; Darvishmotevali et al., 2017; Zeytinoglu et al., 2013). Job insecurity is considered as one of the strongest hindrance stressors that is closely connected with hospitality workplaces (Bakker & Demerouti, 2007) with a wide variety of negative consequences such as anxiety, emotional exhaustion, absenteeism, and low performance. JI is defined as an individual's overall concern for the continued existence of their job in the future (Sverke and Hellgren, 2002). It is considered as a complex phenomenon that not only affects an individual's work related outcomes, but also their work-family-related outcomes (Sverke et al.,

2002). The consequences of this severe stressor can be physical, psychological, and behavioural (Robbins and Judge, 2011). Although a broad range of studies have confirmed the negative causal relationship between JI and different types of employee attitudes and organizational outcomes (Darvishmotevali et al., 2017; Wang et al., 2014; Sender et al., 2017), less is known regarding the mechanism through which JI affects employees' performance via work related well-being, and in particular subjective well-being (Hu et al., 2018). In other words, does job insecurity negatively impact on job performance through decreasing employees' subjective well-being? According to the transactional stress theory (TST), stress will arise when employees are unable to find a suitable coping strategy when they are uncertain about the answer. Similarly, in the JI context, employees are in an uncertain situation about the future of their employment; consequently, in such circumstances, finding a suitable remedy for coping is very difficult and may lead to stress for the employees and negatively impacts on their work-related well-being. Recently, several studies have been conducted on the relationship between JI, SWB, and employees' job performance (Hu et al., 2018; Inanc, 2018). Nevertheless, the mediating mechanism linking JI to job performance (JP) through SWB in the hotel context has not been investigated (Richter and Näswall, 2018). Therefore, to fill this gap, this study uses transactional stress theory to test how JI impacts on employees' JP through decreasing their SWB.

Additionally, because of the high importance of the impact of job

insecurity, especially in the hospitality industry, the present research concurrently seeks to answer this question: how can the negative impact of job insecurity be reduced?

Available research on occupational stress has shown that such stress depends to a large extent on individuals' behaviour such as personality traits and their coping mechanisms (Richter, 2011). Lazarus and Folkman (1984) believe that stress is the result of the unsuccessful interaction between individuals and their environment. However, they also believe that an individual's characteristics and personal resources could help them to cognitively evaluate a situation. Although a number of studies (Hu et al., 2018; Richter and Näswall, 2018; Shoss, 2017) have focused on the personal characteristics as a mediator or moderator to reduce the negative impacts of JI on employees' well-being, none of them have focused on psychological mechanism(s) relating JI and SWB to behavioural outcomes (De Witte et al., 2016; Richter and Näswall, 2018). Particularly, the buffering role of psychological capital (PsyCap) on the impacts of JI on employees' subjective well-being and subsequently their JP has yet to be studied. PsyCap as a composite construct has been defined by Luthans and Youssef (2007) as individuals' positive psychological state of development and is characterized by self-efficacy, optimism, hope, and resilience. As proposed by Richter and Näswall (2018), further studies need to determine psychological factors to prevent or at least minimize the negative consequences of JI; this research aims to examine the buffering role of PsyCap considering its components in order to reduce the negative impacts of JI on employees SWB and subsequently their job performance (see Fig. 1).

Consequently, this study contributes to both the theory and the literature of JI, SWB, PsyCap, and JP in three ways. First, this study investigates to further the understanding of the process of the negative impacts of JI on employees' JP through decreasing employees' SWB, which is highly important for both employees and organizations, particularly in the hospitality industry. Second, this study examines the buffering role of PsyCap to reduce the negative impact of JI on employees' SWB and performance, an area that requires further attention. We believe that hospitality industry is more stressful context than other industries but, individuals are different in their reaction to stressful situations. Therefore, it is necessary to study the personal characteristics of employees who experience JI. Under these conditions, the present study responds to the need for more research (Niesen et al., 2018) regarding the negative psychological consequences of JI and the moderating role of different constructs to prevent, control, or minimize these negative consequences based on transactional stress theory. Third, this study is one of the few studies in the field of hospitality investigating four components of PsyCap as observed variables. Its importance contribution lies in demonstrating the link between hope, self-efficacy, resilience, and optimism as moderators with JI, SWB and JP. This study is one of the first studies in hospitality research investigating individuals' personal resources according to Luthans's psyCap model, which also give this chance to the readers to compare their direct and indirect impacts on outcome variables. In practical

terms, understanding the nature of work stressors and the mechanism how these stressors affect employee's performance is greatly helped managers to find solutions to mitigate the adverse effects of these stressors. PsyCap as a moderator in current study relates to individuals' personal ability in dealing with JI. The study findings give an insight to managers to train their employees and develop their PsyCap as a solution to cope with and minimize the negative impacts of JI at workplace.

2. Literature review and hypotheses

2.1. Job insecurity

Job insecurity (JI), as defined by Greenhalgh and Rosenblatt (1984), refers to "...perceived powerlessness to maintain desired continuity in threatened job situation" (p.438). From an international perspective, Witte (1999) has defined JI as an individual's overall concern regarding their job and its continued existence in the future. Later Hellgren et al. (1999) proposed qualitative and quantitative aspects of JI. Qualitative JI is described as concern regarding the future of a job situation, whereas the quantitative aspect of JI refers to the consequences of losing a job and its valued features, such as the lack of job opportunities, the loss of insurance or a reduction in wages. Both quantitative and qualitative aspects of JI significantly impact on employees' attitudes and performance (i.e., Darvishmotevali et al., 2017; Lee et al., 2018). Sverke and Hellgren (2002) explained JI from different perspectives: cognitive and affective. They believe that cognitive insecurity is related to the employees' perception of the organization; on the other hand, affective insecurity refers to the individual-level assessment of the situation. The importance of distinguishing between cognitive and affective aspects of JI refers to their consequences. Affective insecurity is correlated with psychological strain, while cognitive insecurity is more associated with job attitudes such as engagement, commitment or satisfaction (Bouzari and Karatepe, 2018; Huang et al., 2012; Ištóňová and Fedáková, 2015). In this study, we aim to examine the consequences of JI from the cognitive perspective.

2.2. Psychological capital

Based on trait theory, psychological capital is defined as an individual's personality traits with relative stability and durability. Also, state theory explains that psychological capital refers to a person's mental state, in which individuals can display positive organizational behaviours and demonstrate effective work performance. Luthans and Youssef (2007) believed that the definition of psychological capital should meet the following properties: firstly, it should belong to the field of positive psychology, representing an individual's merits, potential capabilities and positive aspects. Secondly, it is a positive state of mental development that is clearly distinguished from human capital and social capital. Thirdly, it can be measured. The fourth point is that it should also be exploitable. The last property is that psychological capital can affect individuals' performance. Investing in psychological capital can obtain profits, that is to say, a high level of psychological capital can promote positive behaviour, ensure good work performance and improve the competitiveness of an organization or enterprise (Kim et al., 2018; Ozturk and Karatepe, 2018). Undoubtedly, psychological capital is an important resource, which is composed of self-efficacy, optimism, hope and resilience. Self-efficacy is defined as individuals' task-specific self-confidence and the belief that they are able to achieve objectives effectively. Self-efficacy refers to the individuals' beliefs and abilities to succeed in specific conditions or to achieve task' targets. It refers to people's beliefs regarding their capability to produce effects (Bandura, 2010). Optimism is described as not only expecting successful outcomes, but also reacting to issues with high confidence and personal abilities. In the other words, optimistic people are hopeful and confident about future events or the successful results of something.

Fig. 1. Research mediating moderating Proposed Model.

Individuals are optimistic if they interpret positive events to be internal and lasting, whereas they perceive negative events to be external and temporary. In brief, optimism refers to individuals' faith regarding their abilities to improve a situation (Luthans et al., 2015). Hope is an optimistic perspective and attitude of mind that is based on positive outcome expectations related to events and conditions in an individual's life. People are hopeful if they have both the will to achieve a certain goal, and a plan for how it should be attained (Avey et al., 2009). Finally, resilience refers to the ability to spring back and beyond when faced with difficulties and recover quickly from them. In other words, returning to a suitable level of performance and learning from the experience. This does not mean that people should purposefully seek problems, but with resilience, people are capable of developing their ability to cope and thrive when faced with obstacles (Luthans and Youssef, 2007). These components are crucial factors that determine an individual's behaviours. The possession of psychological capital relates to individuals' achievements and well-being; therefore, training and developing it will determine an enterprise's existence, development and prosperity (Chen, 2013).

2.3. Subjective well-being

Well-being is described as global judgments of life satisfaction and emotions range from depression to happiness (Diener et al., 2009). The subject of well-being has been studied by many scholars over the past decades, as well as its various components and aspects such as emotional, physical, economical, and social well-being. Subjective well-being (SWB) has become the subject of heated discussion among researchers due to its contributions to traditional income-based welfare (Angner, 2010). Seligman and Csikszentmihalyi (2000) believe that SWB is a more scientific term for what individuals mean by satisfaction and happiness. SWB is a self-reported measure of well-being, which is defined as individuals' experience of their quality of life. This experience includes cognitive and affective perception and evaluation of life (Diener et al., 2005). The cognitive aspect of SWB refers to what individuals think about their life satisfaction generally (life as a whole) and also in a particular area of life (i.e. job, relationships, etc.). Cognitive evaluation has a significant contribution in individuals' well-being as it underlines one's reaction to positive and negative life experiences. The affective aspect of SWB refers to the individual's emotion, mood and feeling. The affect can be positive when the moods and feelings experienced are pleasant (i.e. pleasure, happiness, love etc.), but it can be negative when the emotions and feelings experienced are not pleasant (i.e. guilt, excitement, confusion etc.). An individual's SWB is related to their positive and negative memories of life events, along with the related emotional reactions to these events. Individuals who have experienced more positive events than negative events in their lives, who have tended to interpret their events positively, remember more positive life events, and feel greater satisfaction and happiness (Seidlitz et al., 1997). Although several scholars have emphasized subjective well-being, which is measured by subjective along with objective measures such as economic or social indicators, Diener (1984) asserted that such objective indicators are seen as potential effects on SWB, but they are not seen as a necessary part of SWB.

2.4. Job performance

Overall, performance refers to the execution of the tasks assigned to the person. What an employee does in the job, or how they carry out the task is called performance. Therefore, performance (the process of operation) is a collection of individual behaviours in relation to the given job. Also, employees' job performance in an organization reflects their knowledge, skills, behaviour, and ethical values. It is the employees' ability to accomplish the expectations of the organization.

However, there are various viewpoints involved in explaining the concept of job performance, and it is widely accepted that job

performance is a multidimensional construct (Campbell et al., 1993).

Campbell et al. (1993) stated that performance must be explained from two perspectives: behavioural and outcome. From the behavioural viewpoint, job performance refers to what employees do or how they behave when they are at work. From the outcome perspective, performance refers to the results of employees' behaviour. In other words, performance can be defined as an evaluation of results. Indeed, the behavioural and outcome aspects of performance are linked together.

Moreover, performance can be broken down into effectiveness and productivity dimensions (Pritchard, 1992). There is a significant difference between productivity and effectiveness. While effectiveness refers to the degree to which something is successful in producing a desired result, productivity is explained as the effectiveness of productive effort, especially in industry, as measured in terms of the rate of output per unit of input.

The aim of organizations is to adopt a best practice approach and create a safe and secure place to lead employees to improved organizational performance, higher levels of service quality and ultimately increases in productivity and profitability.

2.5. Mediating mechanism hypothesis development

Job demand-resource (JD-R) theory (Demerouti et al., 2001) asserts that high job demand is the main predictor of negative work strain. High job demands reduce individuals' psychological and physical resources, which subsequently leads to energy reduction and different physical and mental health problems. According to this theory, job insecurity is considered as a job demand (Rigotti et al., 2015; Schreurs et al., 2014) and refers to the employee's belief regarding their job, which they are at risk of losing. Empirical studies indicate that JI is a severe hindrance work stressor resulting in negative physical, psychological and behavioural consequences and is negatively correlated with different job attitudes and outcomes at individual, team and organizational levels in the workplace (Blom et al., 2018; Costa and Neves, 2017; Wang et al., 2014). Witte (1999) believes that job insecurity firstly reduces individuals' well-being, which subsequently affects on their performance. He believes that JI appears to decrease well-being in both the long and short term. Furthermore, in two meta-analysis studies, JI was found to generate negative impacts on employees' psychological and physical health (Cheng and Chan, 2008; Sverke et al., 2002).

According to Lazarus and Folkman's (1987) transactional stress theory, stress perception and outcomes are part of a dynamic process which includes initial and secondary assessment. Insecure employees perceive the threat of the loss of their job and employee benefits and this is while it is not clear whether it will happen in the future (initial assessment); furthermore, uncertainty about the future makes it very hard to evaluate and choose suitable coping strategies to overcome the insecure condition (secondary assessment). Therefore, in the JI context, the process of assessment leads to rising stress and strain among employees, since the uncertain situation is not easily predictable by fixed strategies and resources, and finding effective coping strategies is complicated. Accordingly, previous studies have shown that feelings of job insecurity correlate with a lower score on various indicators of job-related well-being, like increased levels of emotional and physical exhaustion, suggesting that a prolonged exposure to JI can lead to the depletion of individual resources. In particular, Darvishmotevali et al. (2017) found that JI negatively results in low JP via anxiety and emotional exhaustion as well-being indicators. Stiglbauer and Batinic (2015) showed that JI has a negative impact on employees' happiness and a positive impact on their depression as two main components of SWB. Similar results were also found by Hu et al. (2018), whereas they also showed that employees who experience job insecurity feel less happiness and more depression. These studies reveal that JI is more likely to cause poor well-being among employees. Although the different consequences of JI have been studied in previous research, the

SWB effects of JI and particularly the mediating role of SWB in the JI and employees' performance relationship has not received sufficient attention (Hu et al., 2018; Richter and Näswall, 2018). Therefore, in the current study, we intend to explain the relationship between JI and JP through decreasing SWB as a type of psychological strain which results from workplace stressors. Therefore, it is hypothesized that:

H1. Job insecurity negatively affects employees' job performance via decreasing their subjective well-being.

2.6. Moderating mechanism hypothesis development

The recent growth of job insecurity has clarified its links to employees' well-being (Richter and Näswall, 2018). The theoretical explanation for these correlations refers to the nature of JI as a severe work stressor. In spite of the growing body of quantitative and qualitative studies, which demonstrates that JI harms the physical and mental health of employees, little is known about the suitable coping strategies under insecure job situations (Richter and Näswall, 2018). Since job insecurity is characterized by uncertainty about the future, with the unclear sources of threats and hazards, it implies that remedies and effective coping strategies are also uncertain. Finding a suitable coping strategy under uncertain situations is significantly complicated for employees. In fact, when employees perceive job insecurity, they lose support from the organization; hence, in order to cope or adapt to this stressful situation, they may only rely on their personal resources. Without doubt, personal resources have an important role in coping with stress and managing uncertain situations (Hobfoll, 1989).

Transformational stress theory (Lazarus and Folkman, 1984) attempts to provide more clarity regarding individuals' cognitive assessment in stressful situations and coping situations, and moreover, to realize how cognitive assessments play a significant role in moderating stress response levels. Cognitive evaluation refers to an individual's assessment of a specific situation and focuses on the emerging sources, features, and also evaluating coping reactions encountered with the specific environment. When dealing with events, some individuals may respond with excitement, hostility or frustration, while others may feel anxiety, exhaustion and guilt, and some may even ignore the problem. The manner in which individuals address specific situations is influenced by their beliefs, capacities, abilities, mindsets, commitments and aims. Stress reactions and coping are contextual and can be different for different kinds of individuals and they depend on their cognitive evaluation of the situation. Moreover, conservation of resource (COR) theory (Hobfoll, 1989) asserts that employees with high personal resources will potentially be able to cope with and control job-related stressors. Accordingly, individual differences can be considered as the capital for diminishing the stressors' negative impacts on performance outcomes. Psychological capital (Luthans et al., 2007) as an individual resource and positive psychological state is significant to how employees interpret their environment, available resources, resources' constraints, and how they use the available resources to control the situation (Chadwick and Raver, 2013). This composite construct is found to be largely related to job involvement, mental health, and psychological wellbeing (Mensah and Amponsah-Tawiah, 2016; Setar et al., 2015; Yuan and Wang, 2016). Probst et al. (2017) demonstrated that high levels of psychological capital moderate the JI and JP relationship. However, although related literature has shown the numerous significant impacts of PsyCap on different work constructs, to the authors' knowledge there is no empirical evidence for the impacts of four components of PsyCap on the specific causal relationships in the current study (JI, SWB and JP).

In stressful conditions, successful coping strategies seem to depend on the relation between the nature of the stressors and beliefs about one's capabilities to meet situational demands (Williams et al., 2010). Self-efficacy is an individual's belief in their innate abilities to achieve goals. Personal beliefs of the individual's capacities to respond to

stressful conditions seem to be especially significant for explaining the individual's experience of that stressful condition. Sora et al. (2018) explored the relationships among objective and subjective JI, job and collective self-efficacy, and affective well-being on employees from 138 Spanish and Austrian organizations. The findings consistently showed that subjective JI was negatively related to affective well-being. In addition, both self and collective efficacy moderated the subjective JI-affective well-being relation, ameliorating employees' well-being levels when they perceived JI. Moreover, the quantitative study by Adebayo (2006) tested the moderating role of self-efficacy in the relationship between perceived JI and organizational commitment as a positive job attitude. The results revealed that the relationship between JI and organizational commitment was moderated by self-efficacy such that employees with high levels of self-efficacy showed greater levels of organizational commitment and performance (Adebayo, 2006). High self-efficacy is related to the regulation of the stress process, to higher self-esteem, better psychological and physical well-being, optimal adaptation to unpredictable situation and high performance (Byars-Winston et al., 2017; Stajkovic and Luthans, 1998). Part of the focus of this study is on employees' self-efficacy as a component of PsyCap in an uncertain future of work. Particularly, we investigate the moderating role of self-efficacy in the causal relationship of JI, SWB, and JP. Thus:

H2. Self-efficacy reduces the negative impact of JI on employees' SWB and JP.

Resilience is another component of PsyCap that plays a significant role in individuals' health (Gray and Jones, 2018). Resilience is always important, but it can particularly equip individuals for times of change and stress such as: life and work transitions and changes, starting at a new workplace, uncertain work and life future, or when diagnosed with, or worried about a mental health problem such as anxiety, or emotional exhaustion (Hartmann et al., 2019). Resilience that is directly associated with wellbeing is about having the ability to cope with and adapt to new situations. It is supposed that having a sense of resilience enables individuals to approach other people and situations with confidence and optimism, which is especially important for employees given the enormous changes that have occurred with the transition to new manufacturing processes, which has reduced the demand for human resources (Kimura et al., 2018). We propose that employees with high resilience look at a difficult situation through the lens of realistic optimism and have high confidence to approach new situations and deal with work stressors. Thus:

H3. Resilience reduces the negative impact of JI on employees' SWB and JP.

Optimism as a mental attitude entails expectations and hope about positive outcomes in the future. Generally, they think that future events will be positive, favorable, and desirable (Carver and Scheier, 2014). Bandura (1998) believes that human achievements and positive well-being require an optimistic feeling of personal efficacy to overcome the numerous obstacles to success. The self-regulatory model (Carver and Scheier, 1981) asserts that optimism affects outcomes via its self-regulatory effect. Based on this model, individuals perceive a discrepancy between their current situation and the consequences of their further actions (Liu et al., 2018). In the workplace, if employees perceive that this discrepancy can be lessened and favorable goals can be accomplished, employees continue to make efforts to reach these favorable outcomes (Liu et al., 2018). Zheng et al. (2014) believe that optimism is a buffer against the JI, since optimists are usually looking toward the future events with hope and positive expectations. The results of their quantitative study show that optimism significantly interacts with JI to predict job satisfaction and better job performance. Job performance and satisfaction are reinforced when JI rises among those employees who show a high level of optimism (Zheng et al., 2014). Accordingly, it is expected that optimistic employees will continue to work hard under the uncertain employment situation and will actively deal with the

adversities and stress they encounter, since they believe positive outcomes will be achieved. Thus:

H4. Optimism reduces the negative impact of JI on employees' SWB and JP.

Hope as a positive expectation and desire for a particular thing to happen is one of the primary topics covered by positive psychology (Slezackova, 2017). As a PcyCap component, it is something close to our ultimate goals and spirituality (Alessandri et al., 2018). Hope covers the hoping individual's sensations of attraction to the desirable outcomes, feelings of both confidence and uncertainty about the outcomes (Slezackova, 2017). Luthans and Youssef (2007) note that hopeful employees tend to work harder and longer in an uncertain work situation in order to show their value to the organization in the hope of securing their employment. The findings of a study by Malinowski and Lim (2015), who investigated the role of hope in employees' general wellbeing on a sample of 299 adults in full-time employment, show that maintaining hope in the workplace is important in the adaptation to stressors and increases employees general well-being (Malinowski and Lim, 2015). Accordingly, we propose that hopeful employees may cope with stress from JI, and this reduces the negative impact of JI on employees' SWB and consequently JP. Thus:

H5. Hope reduces the negative impact of JI on employees' SWB and JP.

3. Methodology

3.1. Sample and procedure

The judgmental sampling procedure (Karatepe and Baddar, 2006) was applied in four-and five-star hotels located in Tehran (the largest city and the capital of Iran) in order to collect data to test the proposed hypotheses. The logic behind purposely selecting hotels with such ratings refers to their emphasis on employee excellence with well-structured and dedicated teams with in-depth management levels, in addition to exceptional levels of quality and productivity as well as effective customer service and performance (UK Hotel Star Rating System, 2013). In 2017, through a letter from the Cultural Heritage, Handicrafts and Tourism Organization of Iran and an explanation of the aims of our research, the management of 13 hotels agreed to participate in the survey. In partnership with one of the researchers, a responsible senior staff member within each of the hotels distributed envelopes to the broad range of employees who were willing to participate in the study. These envelopes included a questionnaire and instructions on how to complete the survey (e.g. no right or wrong answers to the items), as well as information on the anonymity and confidentiality of the responses and the voluntary nature of the survey. All respondents were asked to self-administer the items as honestly as possible, and then return the filled questionnaire to the responsible person in a sealed envelope. In addition, to increase the survey response rate, we offered a reward to employees responding to the items. Multiple respondents were used to evaluate study constructs, whereby employees completed the questionnaire with items that were intended to measure job insecurity, psychological capital and their subjective wellbeing, while supervisors completed questionnaires about each of their employees' job performance (Ketchen et al., 2006; Podsakoff et al., 2003). We did the matching process via identification codes. By paying utmost attention to the issue of confidentiality, the researcher prepared a master list containing the name of each employee in the hotels. Each employee in this master list had an identification number. An identification number was also written on each questionnaire. This procedure was used for both type of questionnaire (employees and supervisors) so that the questionnaires could be matched. This process is consistent with data collection process employed by Bouzari and Karatepe (2018), and Ozturk and Karatepe (2018).

Several procedural remedies were applied to minimize potential

common method bias (CMB) during the data collection process, as Spector (2006) argued that the threat of CMB is generally exaggerated. First, different cover stories for each measurement scale to achieve psychological separation among respondents. Second, the questionnaire only included 26 items. Therefore, it was short enough to avoid tiredness and confusion, which could have a negative impact on the cognitive effort of the respondents to answer the items accurately. Third, the order of the items was counterbalanced, decreasing the threat of respondent "guessing" (Malhotra et al., 2006). Fourth, the language of the items was kept simple, specific, and conscious and by conducting a pilot study among 12 employees and 3 supervisors, the adequacy of the research instruments was verified (Podsakoff et al., 2003). Out of the 280 employees-supervisors dyads, a total of 250 employees and 21 supervisors completed the questionnaires (89% response rate).

Based on our expected response rate, the male employees constitute the major percentage of the workforce, which is 62% ($n = 155$). Eighty two percent ($n = 204$) of the respondents were married and the rest ($n = 46$) were single. Thirty eight percent ($n = 95$) of the sample were between the ages of 38 and 47, while only five percent ($n = 13$) were between 28–37 years of age. In terms of education, 43.2% ($n = 108$) of the respondents had an undergraduate degree and approximately 31% ($n = 77$) had completed vocational school.

3.2. Measurements

All variables were measured using multi-items taken from previous related studies (Table 1). Four items from De Witte (2000) were used to evaluate job insecurity. Psychological capital was measured by twelve items from Luthans et al. (2008), which were also used by Avey et al. (2011), and Costa and Neves (2017). This 12-item included three items for self-efficacy, three items for resilience, four items for hope, and two items for optimism. Subjective wellbeing was measured using five items by the Satisfaction With Life Scale developed by Diener, Emmons, Larsen, and Griffin (1985), which is a widely used and well-validated instrument (Chopik et al., 2017; Gomez et al., 2009; Rojas, 2007; Western and Tomaszewski, 2016). Finally, five items measured performance adapted from Babin and Boles (1998).

3.3. Data analysis

The data were analyzed using a consistent PLS algorithm to conduct confirmatory factor analysis (CFA) for testing the construct validity and internal consistency reliability (Ali et al., 2018). In addition, Structural Equation Modelling was employed to evaluate whether the seven-factor model (JI, JP, SWB, and four components of PsyCap) fit to the available data. Hierarchical multiple regression was used to test the mediation and moderated mediation model.

4. Results

4.1. Reliability and validity

In the first step of the analysis, the reliability and validity of the measurement model were tested. Internal consistency of the measurements was evaluated by internal consistency reliability (composite reliability, CR). The CRs value ranged from 0.753 to .911, which were above the commonly accepted threshold of 0.70 (F. Hair et al., 2014).

Besides, convergent validity (average variance extracted, AVE) and discriminant validity (Fornell-Larcker criterion) were tested to evaluate construct validity of the measurements (Bagozzi, 1992; Cheung and Wang, 2017; F. Hair et al., 2014). The AVEs value ranged from 0.472 to .718, which is confirmed convergent validity as described by Cheung and Wang (2017) that convergent validity is acceptable if AVE is not significantly smaller than 0.5 and standardized factor loadings of all items are not significantly less than 0.5. In addition, in order to establish discriminant validity, the square root of each constructs' AVE

7-JP	-.495*	.370*	.161**	.201*	.237*	.213*	(.796)

Note: * $P < .001$, ** $P < .05$ (2-tailed test). The square root of AVE for each variable is shown on the parentheses with italic font. The HTMTs are shown at the upper triangular of the matrix with italic font.

was calculated (Fornell and Larcker, 1981). As shown in Table 2, the square root of the AVEs (on the diagonal) for each construct is greater than the correlations between it and all other constructs in the model. Moreover, the results of Heterotrait-Monotrait Ratio (HTMT) which is strongly recommended technique to diagnose discriminant validity were below the commonly accepted threshold of 0.85 (Kline, 2011) confirmed the discriminant validity of the measurement (see Table 2). Taken together, these results indicate that common method bias is not a threat in the present study. Table 1 shows all constructs factor loadings, t-value, AVE and CR.

4.2. Mediating mechanism hypothesis test

As can be seen in Table 3, the results show that JI has a negative direct effect on employees' JP ($\beta = -0.557$; $p < .001$). This means that high JI results in low performance. In addition, the results show that SWB has a positive significant direct effect on employees' JP ($\beta = .406$; $p < .001$). In support of H1, the mediating analysis result confirms our hypothesis that JI affects employees' SWB ($\beta = -0.347$; $p < .001$), and by decreasing their SWB ($\beta = .239$; $p < .05$), has a negative impact on their JP. Moreover, the result shows that SWB partially mediates the negative impact of JI on JP since both direct and indirect effects are significant (see Fig. 2).

4.3. Moderating mechanism hypothesis test

The results of four interaction analysis based on PsyCap' four components have been shown in Table 4 separately. Moderated regression analysis for each moderator has been done both directly and indirectly using PLS as recommended by Ali et al. (2018), which have stated the increasing use of PLS in hospitality research, especially where moderators are tested in the model. In detail, the results of direct analysis show the positive and significant interaction effect of JI $\times$ self-efficacy ($\beta = .143$; $p < .05$), JI $\times$ resilience ($\beta = .193$; $p < .05$), JI $\times$ hope ($\beta = .164$; $p < .05$), and JI $\times$ optimism ($\beta = .218$; $p < .05$) on employees' SWB. In addition, the results of direct analysis show the positive and significant interaction effect of JI $\times$ self-efficacy ($\beta = .177$; $p < .01$), JI $\times$ resilience ($\beta = .255$; $p < .01$), JI $\times$ hope ($\beta = .270$; $p < .001$), and JI $\times$ optimism ($\beta = .218$; $p < .05$) on employees' JP. The results of indirect moderated regression analysis also show the positive and significant effect of JI $\times$ self-efficacy ($\beta = .173$; $p < .01$), JI $\times$ resilience ($\beta = .183$; $p < .10$), JI $\times$ hope ($\beta = .162$; $p < .05$), and JI $\times$ optimism ($\beta = .216$; $p < .05$) on employees' SWB and the improvement in their performance. In this way, H2, H3, H4, and H5 are all supported. The results of path analysis are graphically displayed in Fig. 2.

5. Conclusion

5.1. Discussion

The objective of the current research is twofold: first, to extend and test a conceptual model that investigates subjective well-being (SWB) as a mediator of the impacts of job insecurity (JI) on employees' job performance (JP), and second, to develop a moderating model of psychological capital (PsyCap) in the mentioned causal relationship. In other words, the PsyCap capacities of resilience, optimism, self-efficacy, and hope, would serve as a moderating individual resource to lessen the negative impacts of JI on SWB and JP. To achieve these objectives, a model was designed based on previous literature and relevant existing theories (transactional stress theory, JD-R theory, & COR theory), and then a series of analyses were conducted based on data collected from 250 employees who were working in different departments in four and five star hotels in Tehran.

The results support the proposed mediating role of SWB, linking the JI and JP first hypothesis, therefore confirming that JI negatively impacts employees' JP via decreasing their SWB. This finding deepens our understanding of how JI psychologically impacts on individuals' JP in a negative way. According to the JD-R theory, it seems that job insecurity, as a hindrance work stressor, negatively impacts on employees SWB. SWB refers to an individual's evaluation of how their life is going, defined by high life satisfaction, low negative affect, and high positive affect (Diener, 2009). Employees have high work-related SWB if they are satisfied with their work and they experience frequent positive and negative feelings at work (Bakker and Oerlemans, 2011). In a condition of JI, employees experience lower levels of SWB because they encounter the possibility of losing their most important employment-related

Table 3
Mediating analysis.

Predictors	Criterion Variables			
	Direct effect			Indirect effect
	JP	SWB	JP	JI-SWB-JP
	$\beta(t)$	$\beta(t)$	$\beta(t)$	$\beta(t)$
<i>predictors</i>

Fig. 2. Final structural model and results of path analysis.

resource, which may meet their different needs. Consistent with transactional stress theory, in an insecure situation, the evaluation process results in stress, anxiety and strain, since an uncertain situation in the future makes it difficult to apply a suitable coping strategy. These findings support previous findings in the field of JI (e.g. Hu et al., 2018; Richter and Näswall, 2018), which is also in line with research by Darvishmotevali et al. (2017), where anxiety as an indicator of SWB was found to be significant as a mediating variable in the JI and employees' performance relationship in the hotel industry.

The results support the proposed moderating role of psychological capital, therefore confirming that the negative impact of JI on employees' SWB and JP is decreased by PsyCap. The results are consistent with Lazarus and Folkman (1984), who asserted that the way employees appraise an issue or a situation directly affects their coping processes and emotional reactions, emphasising the significant role of cognitive evaluation in mediating thoughts, emotions and actions and identifying a suitable coping strategy, which results in improved outcomes. The results reveal that PsyCap increases the stress tolerance among employees and their positive perception of surrounding events. Employees with high positive psychology capital feel positive towards issues around them. They also feel confident and are able to evaluate the different aspects of situations and increase the possibility of overcoming stress and difficulties.

As had been predicted in the current study, self-efficacy as a component of PsyCap buffers the negative impacts of JI on SWB and more JP. This result is in line with the findings of other studies that self-efficacy is a moderating construct in the job insecurity – work outcomes relationship (e.g. Adebayo, 2006). High self-efficacy is correlated with higher self-confidence and esteem, positive emotions, high well-being, better mental and physical health, and better adaptation to challenging situations. Self-efficacy representing employees' perceptions of their capacity to manage stressful conditions, will view work stressors as being challenging and less threatening. Employees with high self-efficacy set ambitious goals for themselves and are responsible for performing difficult tasks to achieve those goals. They welcome challenges and work hard to cope with the challenges.

Furthermore, the results show that resilience as a PsyCap component not only has a significant impact on the study outcomes, but it

more than that moderates the negative impact of JI on SWB and JP. The findings confirm the validity of the overall viewpoint, which asserts that resilience is essential to control and overcome the negative and harmful consequences of JI. This result supports the assertion that the ability to approach threats and risk in an adaptive manner is a critical skill in an insecure period (Shoss et al., 2018). Resilience refers to the employees' willingness to deal with stressors in a highly compatibility mode. Resilient employees easily accept the facts of a situation. They have great potential for rapid adaptation to major changes and are capable of achieving their goals even when faced with threats. Indeed, employees with high resilience are able to recover from workplace challenges, and improve themselves based on difficulties.

Optimism is a major construct in positive psychology. Scheier and Carver (2003) described optimism as a set of generalized positive outcome expectancies. Accordingly, employees who generally believe that their good outcomes will outweigh the bad in the future are optimistic. Positive thinking and being optimistic is the first thing that employees need to do in insecure situations. They know and remember that whenever a door closes for them, another one will surely open. Optimists control how they perceive JI. They look at this situation as an adventure and the opportunity to experience something new, which may be more challenging and rewarding. The important point is that in psychological capital, real optimism plays an important role in improving self-efficacy (Scheier and Carver, 2003). In general, optimism is a major contributor to employee well-being. Optimism affects employees' satisfaction, well-being, and job fulfilment through personal development, a sense of purpose in the workplace, positive communication with others, and their general levels of happiness.

The results show that through cognitive appraisal, hopeful employees evaluate the JI situation as less threatening. Hope requires an agency or kind of energy to pursue the goals. In addition, another hope-forming element is planning to achieve the goal, which not only involves identifying targets, but also encompasses different methods to achieve targets. Hope impacts on employees coping with JI by increasing the motivation to cope with a given situation. They are continually searching for alternatives ways to achieve their goals when the original options are blocked. The willpower of employees with high hope helps them to cope successfully with different barriers/challenges

that lead to issues including stress. It can be concluded that in stressful situations such as JI, highly hopeful employees have the ability to distinguish among alternatives for actions that stimulate their energy and create a sense of power and control rather than helplessness. Hopeful people never give up, they are always looking for a solution to problems and they hope that the solutions will reach the desired results.

Ultimately, whilst the personality power in affecting SWB is significant in terms of predisposing individuals to behave in a certain way, their own attempts are also of importance. For instance, the individuals' capacity to change the way they think regarding their life should be considered. Employees with high PsyCap could learn to be more optimistic by changing their explanatory thinking style. How individuals appraise their surrounding events can influence how they will attempt to interact with them.

5.2. Theoretical contribution

Theoretically, the results of the present study add to the existing literature on JI, SWB, PsyCap, JP by examining their causal relationships in the hospitality industry based on psychological work related theories. We tested the mediating role of SWB, in addition to the moderating role of PsyCap in the causal relationship of JI and JP based on transactional stress theory, COR theory and JD-R theory.

The first aim of the current study was to contribute to the mechanism by which JI effects employees' performance. Accordingly, this research provides theoretical contributions to our understanding of the nature of JI: we have endeavoured to explain the mediating process by means of work-related stress theories. Although there has been an increased interest in the examination of mediating constructs between JI and its outcomes, to our knowledge, the current study is among the first to test the process of the JI-JP relationship through the mediating role of SWB. Subjective well-being has been studied as a consequence of JI (Hu et al., 2018), but has not been examined as a mechanism linking JI and employees' JP. As proposed by Richter and Näswall (2018), in order to investigate new mechanisms and potential mediators, SWB was chosen as a mediator to explain the new mechanism through which JI impacts on JP. In addition, transactional stress theory was applied to explain how JI leads to low performance through the intermediary role of SWB.

The second aim of the study was to enhance our understanding of the study variables in the mentioned relationship by considering the buffering role of PsyCap. A review of past research shows that researchers have made efforts to determine the factors that have the possibility of reducing the negative consequences of JI (physical, psychological and behavioural). However, the interaction with JI to improve SWB has not been investigated in detail. As suggested by Richter and Näswall (2018) and Hu et al. (2018), the buffering interventions to prevent or minimize the negative impacts of JI on its psychological outcomes need to be thoroughly investigated. Therefore, the current study is among the first to examine psychological capital as a buffer to minimize the negative impacts of JI on employees' SWB and JP, and thus has the potential to contribute to the literature on the study variables. Applying transactional stress theory to explain the moderating role of PsyCap is also a remarkable contribution to the literature. Based on this theory, we explain that psychological capital helps employees in the cognitive appraisal of environmental issues (job insecurity) and how to cope with any harmful stimuli.

5.3. Practical contribution

The hotel environment is characterized by shift work, long working hours, few breaks, seasonality, and a lack of unionization. In general, hotel work is tied to insecurity. Hotel directors must accept the fact that JI in most cases is a hindrance stressor with severe negative consequences, such as low well-being, low performance and extreme physical problems. With this knowledge, hotel management teams

should make appropriate and constructive decisions to minimize the negative consequences of JI.

In the organizational and strategic management field, employees' physical and psychological health issues are very important and psychological health in particular is a basic requirement for the employees to apply their intelligence. Managers must care more about the positive inner resources of their staff to improve organizational outcomes than advanced technologies, experience, or skill. They must invest in the development of employees' PsyCap and their positive capacities. In the competitive and uncertain context of hospitality, it is undeniable that human resources represent the most significant source of competitive advantage for organizations. The current research demonstrates that under JI, employees with high PsyCap are more successful in coping with stress and demonstrate an acceptable level of performance. Therefore, practical strategies for enhancing employees' positive psychological resources should be developed to help them better adjust to their working situations.

The psychological capital intervention (PCI) model (Luthans et al., 2006) is an educational model designed and developed to enhance psychological capital. This model asserts that the PsyCap can actually be developed through face-to-face training, which will improve the employees' efficiency (Luthans et al., 2010). Through educational program and service institutions, managers may increase employees' PsyCap, improve their mental health and their performance, and decrease employees' negative attitudes in the workplace. By providing effective training programs and using modern leadership practices, management teams may improve employees' positive PsyCap. In the first step, they can familiarize employees with the organization goals and inform them about their significant contribution in achieving these goals. Then, selecting and informing employees about their positive characteristics and abilities (in many cases employees are unaware of their abilities) is a crucial step to improve their PsyCap. Teaching them how to create and improve positive internal attributes can be effective. By applying unfavourable events analysis techniques, managers may improve employees' optimism levels through focusing on positive outcomes. Introducing different problem-based strategies can be another tactic in developing employees' resilience levels. Moreover, using past successes and mastery experiences may be effective to build employees confidence and improve their self-efficacy levels. In addition, through establishing training programs and systematic human resource policies within the hotels, managers can reduce the impact of the work stressors, with the aim of producing more efficient employees. Managers must know that employees with rich personal resources will usually concentrate on problem-focused coping strategies, rather than emotional responses such as distancing or wishful thinking. In order to improve employee retention, a well-established monitoring system should be implemented with the help of experienced employees, who can also serve as mentors or role models.

Moreover, organizational level interventions such as employees' participation in the planning, information sharing, implementation, and evaluation of activities to sustain the desired outcomes are proposed to manage JI during organizational restructuring. Such strategies for those companies that want to reduce workforce can be much less damaging to personnel. Because personnel will be involved in the decision-making process and the development of the organization at the right time and can make better decisions, they will therefore suffer less damage.

5.4. Limitations

The authors recognize that this work has some limitations, which are also opportunities for further research. First, since subjective well-being has been correlated to different job attitudes and performance outcomes such as work engagement, commitment, OCB, and in-role or extra-role customer service, more research is proposed to extend and evaluate strategies to promote subjective well-being in employees. Strategies such as workplace spirituality, performance feedback,

autonomy, servant or transformational leadership are strongly recommended.

Second, in the current study, employee performance as a behavioural consequence of JI has been examined. It is proposed that prospective studies should focus on other types of JI consequences, such as negative job attitudes, different job performance, and most importantly, customer satisfaction in the case of frontline employees. Collecting longitudinal data in other service industries such as service marketing or the healthcare industry is recommended.

Third, in the present study, different statistical remedies have been applied to control CMB. It is recommended to future researchers to use other techniques, which would be those with a measured or unmeasured marker variable.
